# **Chapter 5: CPU Scheduling**

#### **Outline**

- Basic Concepts
- Scheduling Criteria
- Scheduling Algorithms
- Thread Scheduling
- Multi-Processor Scheduling
- Real-Time CPU Scheduling
- Operating Systems Examples
- Algorithm Evaluation

#### **Objectives**

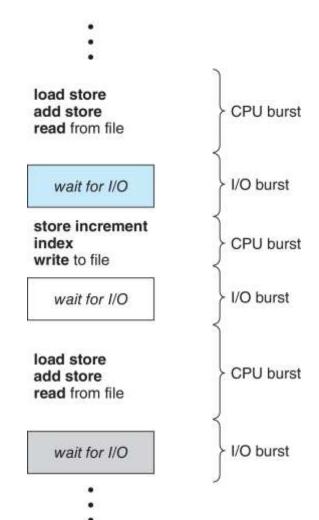

- Describe various CPU scheduling algorithms
- Assess CPU scheduling algorithms based on scheduling criteria
- Explain the issues related to multiprocessor and multicore scheduling
- Describe various real-time scheduling algorithms
- Describe the scheduling algorithms used in the Windows, Linux, and Solaris operating systems
- Apply modeling and simulations to evaluate CPU scheduling algorithms

#### **Basic Concepts**

- Maximum CPU utilization obtained with multiprogramming
- CPU–I/O Burst Cycle Process execution consists of a cycle of CPU execution and I/O wait
- CPU burst followed by I/O burst
- CPU burst distribution is of main concern

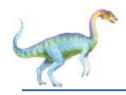

#### **CPU Scheduler**

- The CPU scheduler selects from among the processes in ready queue, and allocates a CPU core to one of them
  - Queue may be ordered in various ways
- CPU scheduling decisions may take place when a process:
  - 1. Switches from running to waiting state
  - 2. Switches from running to ready state
  - 3. Switches from waiting to ready
  - 4. Terminates
- For situations 1 and 4, there is no choice in terms of scheduling. A new process (if one exists in the ready queue) must be selected for execution.
- For situations 2 and 3, however, there is a choice.

#### **Preemptive and Nonpreemptive Scheduling**

- When scheduling takes place only under circumstances 1 and 4, the scheduling scheme is nonpreemptive.
- Otherwise, it is preemptive.
- Under Nonpreemptive scheduling, once the CPU has been allocated to a process, the process keeps the CPU until it releases it either by terminating or by switching to the waiting state.
- Virtually all modern operating systems including Windows, MacOS, Linux, and UNIX use preemptive scheduling algorithms.

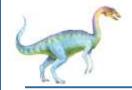

# **Preemptive Scheduling and Race Conditions**

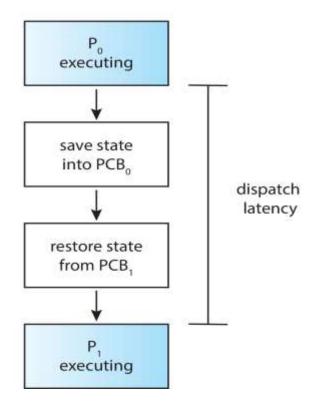

- Preemptive scheduling can result in race conditions when data are shared among several processes.
- Consider the case of two processes that share data. While one process is updating the data, it is preempted so that the second process can run. The second process then tries to read the data, which are in an inconsistent state.
- This issue will be explored in detail in Chapter 6.

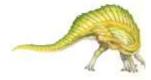

#### **Dispatcher**

- Dispatcher module gives control of the CPU to the process selected by the CPU scheduler; this involves:
  - Switching context
  - Switching to user mode
  - Jumping to the proper location in the user program to restart that program
- Dispatch latency time it takes for the dispatcher to stop one process and start another running

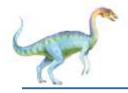

## **Scheduling Criteria**

- CPU utilization keep the CPU as busy as possible
- Throughput # of processes that complete their execution per time unit
- Turnaround time amount of time to execute a particular process
- Waiting time amount of time a process has been waiting in the ready queue
- Response time amount of time it takes from when a request was submitted until the first response is produced.

# **Scheduling Algorithm Optimization Criteria**

- Max CPU utilization
- Max throughput
- Min turnaround time
- Min waiting time
- Min response time

5.10

### First-Come, First-Served (FCFS) Scheduling

<u>Process</u>	Burst Time	
$P_1$	24	
$P_2$	3	
$P_3$	3	

• Suppose that the processes arrive in the order:  $P_1$ ,  $P_2$ ,  $P_3$ The Gantt Chart for the schedule is:

	P <sub>1</sub>	P <sub>2</sub>	P <sub>3</sub>
C	)	4 2	.7 30

- Waiting time for  $P_1 = 0$ ;  $P_2 = 24$ ;  $P_3 = 27$
- Average waiting time: (0 + 24 + 27)/3 = 17

# FCFS Scheduling (Cont.)

Suppose that the processes arrive in the order:

$$P_2$$
,  $P_3$ ,  $P_1$ 

The Gantt chart for the schedule is:

- Waiting time for  $P_1 = 6$ ;  $P_2 = 0$ ;  $P_3 = 3$
- Average waiting time: (6 + 0 + 3)/3 = 3
- Much better than previous case
- Convoy effect short process behind long process
  - Consider one CPU-bound and many I/O-bound processes

# **Shortest-Job-First (SJF) Scheduling**

- Associate with each process the length of its next CPU burst
  - Use these lengths to schedule the process with the shortest time
- SJF is optimal gives minimum average waiting time for a given set of processes
- Preemptive version called shortest-remaining-time-first

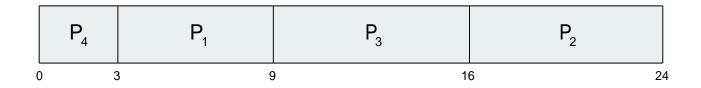

#### **Example of SJF**

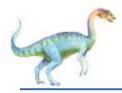

<u>Process</u>	Burst Time
$P_1$	6
$P_2$	8
$P_3$	7
$P_4$	3

SJF scheduling chart

• Average waiting time = (3 + 16 + 9 + 0) / 4 = 7

# **Shortest Remaining Time First Scheduling**

- Preemptive version of SJN
- Whenever a new process arrives in the ready queue, the decision on which process to schedule next is redone using the SJN algorithm.
- Is SRT more "optimal" than SJN in terms of the minimum average waiting time for a given set of processes?

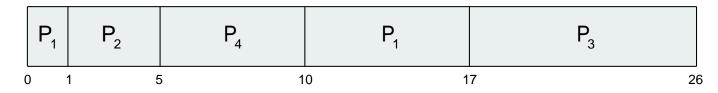

#### **Example of Shortest-remaining-time-first**

 Now we add the concepts of varying arrival times and preemption to the analysis

<u>Process</u>	<u> Arrival Time</u>	Burst Time
$P_1$	0	8
$P_2$	1	4
$P_3$	2	9
$P_4$	3	5

Preemptive SJF Gantt Chart

• Average waiting time = [(10-1)+(1-1)+(17-2)+(5-3)]/4 = 26/4 = 6.5

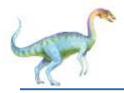

# Round Robin (RR)

- Each process gets a small unit of CPU time (time quantum q), usually 10-100 milliseconds. After this time has elapsed, the process is preempted and added to the end of the ready queue.
- If there are n processes in the ready queue and the time quantum is q, then each process gets 1/n of the CPU time in chunks of at most q time units at once. No process waits more than (n-1)q time units.
- Timer interrupts every quantum to schedule next process
- Performance
  - q large ⇒ FIFO (FCFS)
  - $q \text{ small} \Rightarrow RR$
- Note that q must be large with respect to context switch, otherwise overhead is too high

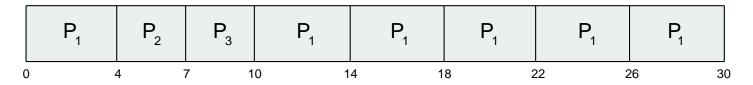

### **Example of RR with Time Quantum = 4**

<u>Process</u>	Burst Time
$P_1$	24
$P_2$	3
$P_3$	3

The Gantt chart is:

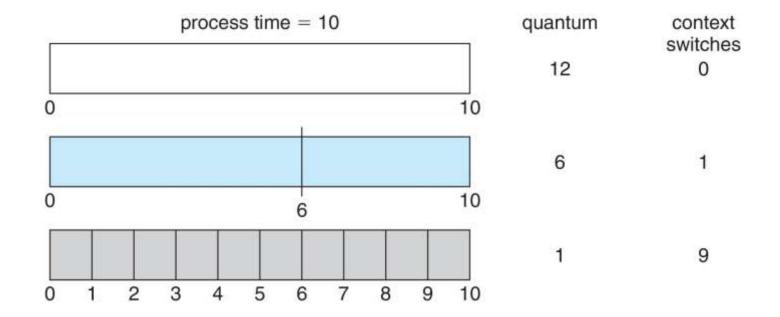

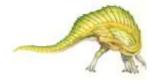

- Typically, higher average turnaround than SJF, but better response
- q should be large compared to context switch time
  - q usually 10 milliseconds to 100 milliseconds,
  - Context switch < 10 microseconds</li>

# **Time Quantum and Context Switch Time**

## **Priority Scheduling**

- A priority number (integer) is associated with each process
- The CPU is allocated to the process with the highest priority (smallest integer = highest priority)
  - Preemptive
  - Nonpreemptive
- SJF is priority scheduling
- Problem = Starvation low priority processes may never execute
- Solution = Aging as time progresses increase the priority of the process

### **Example of Priority Scheduling**

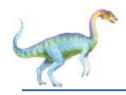

<u>Process</u>	<b>Burst Time</b>	<b>Priority</b>
$P_1$	10	3
$P_2$	1	1
$P_3$	2	4
$P_4$	1	5
$P_5$	5	2

Priority scheduling Gantt Chart

Average waiting time = 8.2

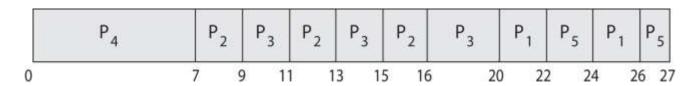

# **Priority Scheduling w/ Round-Robin**

- Run the process with the highest priority. Processes with the same priority run round-robin
- Example:

<u>Process</u>	<b>Burst Time</b>	<u>Priority</u>
$P_1$	4	3
$P_2$	5	2
$P_3$	8	2
$P_4$	7	1
$P_5$	3	3

Gantt Chart with time quantum = 2

#### **Multilevel Queue**

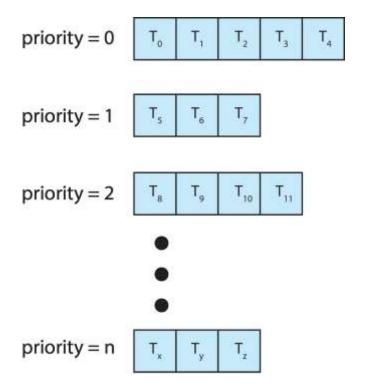

- The ready queue consists of multiple queues
- Multilevel queue scheduler defined by the following parameters:
  - Number of queues
  - Scheduling algorithms for each queue
  - Method used to determine which queue a process will enter when that process needs service
  - Scheduling among the queues

#### **Multilevel Queue**

- With priority scheduling, have separate queues for each priority.
- Schedule the process in the highest-priority queue!

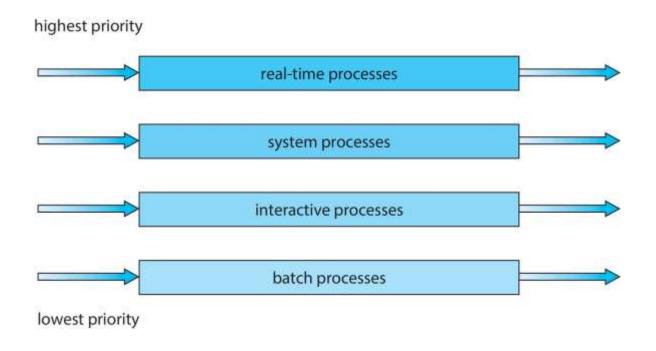

#### **Multilevel Queue**

Prioritization based upon process type

#### Multilevel Feedback Queue

- A process can move between the various queues.
- Multilevel-feedback-queue scheduler defined by the following parameters:
  - Number of queues
  - Scheduling algorithms for each queue
  - Method used to determine when to upgrade a process
  - Method used to determine when to demote a process
  - Method used to determine which queue a process will enter when that process needs service
- Aging can be implemented using multilevel feedback queue

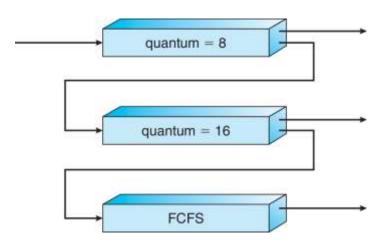

### **Example of Multilevel Feedback Queue**

#### Three queues:

- $Q_0$  RR with time quantum 8 milliseconds
- Q<sub>1</sub> RR time quantum 16 milliseconds
- $Q_2 FCFS$

#### Scheduling

- A new process enters queue Q<sub>0</sub> which is served in RR
  - When it gains CPU, the process receives 8 milliseconds
  - ▶ If it does not finish in 8 milliseconds, the process is moved to queue Q₁
- At Q<sub>1</sub> job is again served in RR and receives 16 additional milliseconds
  - If it still does not complete, it is preempted and moved to queue Q<sub>2</sub>

### **Thread Scheduling**

- Distinction between user-level and kernel-level threads
- When threads supported, threads scheduled, not processes
- Many-to-one and many-to-many models, thread library schedules user-level threads
  - Known as process-contention scope (PCS) since scheduling competition is within the process
  - Typically done via priority set by programmer
- Kernel thread scheduled onto available CPU is system-contention scope (SCS) – competition among all threads in system

# **Multiple-Processor Scheduling**

- CPU scheduling more complex when multiple CPUs are available
- Multiprocess may be any one of the following architectures:
  - Multicore CPUs
  - Multithreaded cores
  - Heterogeneous multiprocessing

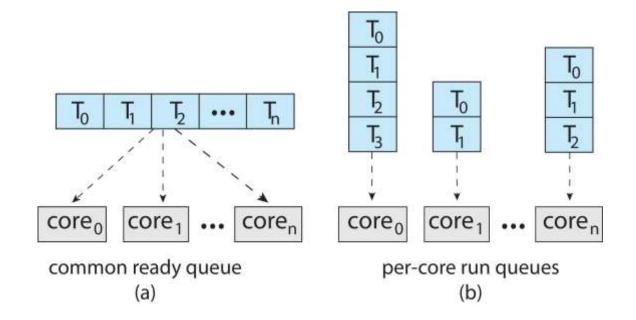

5.29

### Multiple-Processor Scheduling

- Symmetric multiprocessing (SMP) is where each processor is self scheduling.
- All threads may be in a common ready queue (a)
- Each processor may have its own private queue of threads (b)

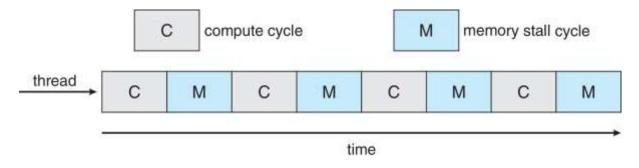

#### **Multicore Processors**

- Recent trend to place multiple processor cores on same physical chip
- Faster and consumes less power
- Multiple threads per core also growing
  - Takes advantage of memory stall to make progress on another thread while memory retrieve happens
- Figure

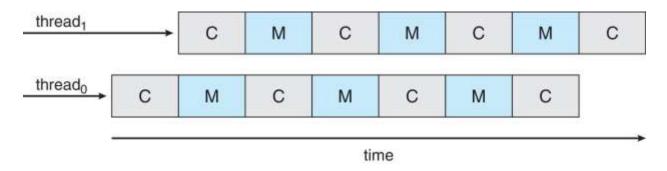

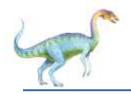

### **Multithreaded Multicore System**

- Each core has > 1 hardware threads.
- If one thread has a memory stall, switch to another thread!
- Figure

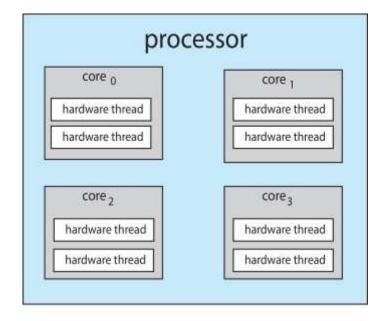

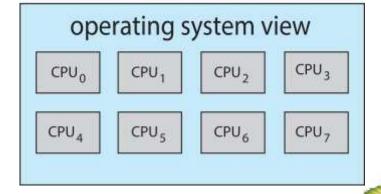

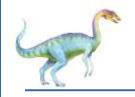

## **Multithreaded Multicore System**

Chip-multithreading (CMT)
 assigns each core multiple
 hardware threads. (Intel refers
 to this as hyperthreading.)

 On a quad-core system with 2 hardware threads per core, the operating system sees 8 logical processors.

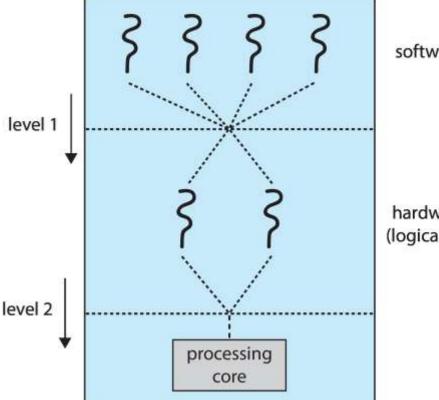

#### **Multithreaded Multicore System**

5.34

- Two levels of scheduling:
  - The operating system deciding which software thread to run on a logical CPU

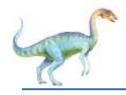

2. How each core decides which hardware thread to run on the physical core.

software threads

hardware threads (logical processors)

#### **Multiple-Processor Scheduling – Load Balancing**

- If SMP, need to keep all CPUs loaded for efficiency
- Load balancing attempts to keep workload evenly distributed
- Push migration periodic task checks load on each processor, and if found pushes task from overloaded CPU to other CPUs
- Pull migration idle processors pulls waiting task from busy processor

#### **Multiple-Processor Scheduling – Processor Affinity**

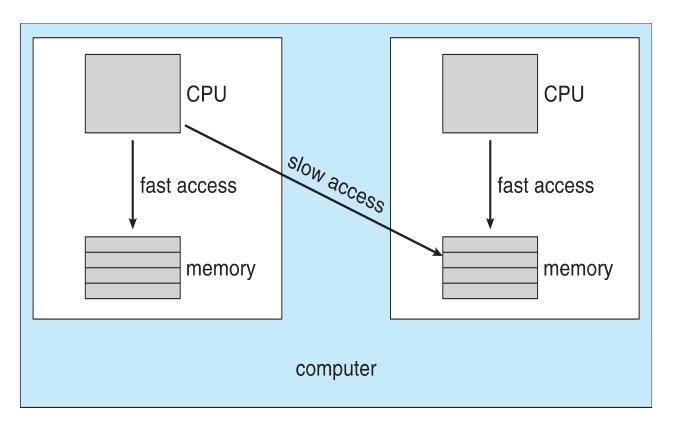

- When a thread has been running on one processor, the cache contents
  of that processor stores the memory accesses by that thread.
- We refer to this as a thread having affinity for a processor (i.e., "processor affinity")
- Load balancing may affect processor affinity as a thread may be moved from one processor to another to balance loads, yet that thread loses the contents of what it had in the cache of the processor it was moved off of.
- Soft affinity the operating system attempts to keep a thread running on the same processor, but no guarantees.
- Hard affinity allows a process to specify a set of processors it may run on.

### **NUMA** and CPU Scheduling

If the operating system is **NUMA-aware**, it will assign memory closes to the CPU the thread is running on.

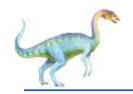

### **Real-Time CPU Scheduling**

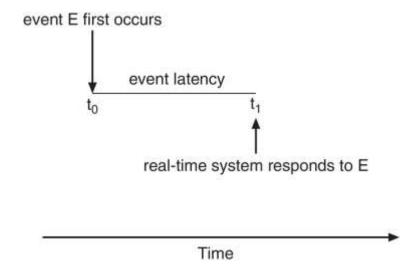

- Can present obvious challenges
- Soft real-time systems Critical real-time tasks have the highest priority, but no guarantee as to when tasks will be scheduled
- Hard real-time systems task must be serviced by its deadline

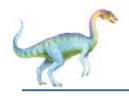

### Real-Time CPU Scheduling

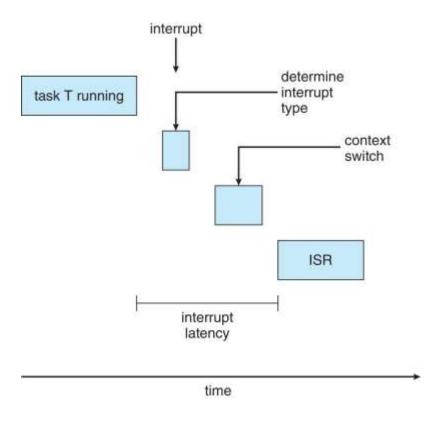

- Event latency the amount of time that elapses from when an event occurs to when it is serviced.
- Two types of latencies affect performance
  - Interrupt latency time from arrival of interrupt to start of routine that services interrupt
  - Dispatch latency time for schedule to take current process off CPU and switch to another

# **Interrupt Latency**

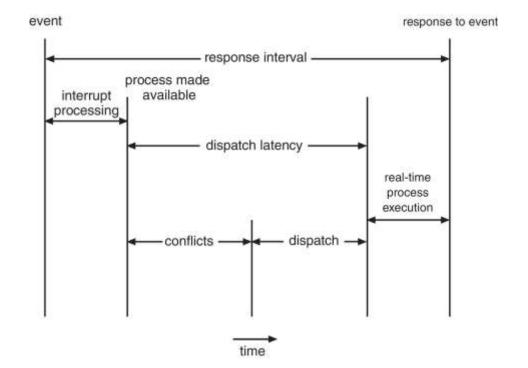

#### **Dispatch Latency**

- Conflict phase of dispatch latency:
  - Preemption of any process running in kernel mode
  - 2. Release by lowpriority process of resources needed by highpriority processes

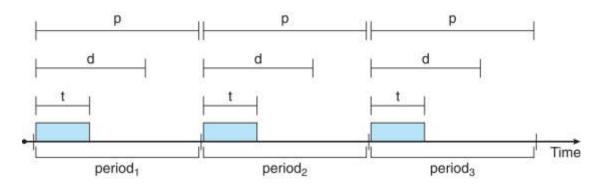

## **Priority-based Scheduling**

- For real-time scheduling, scheduler must support preemptive, prioritybased scheduling
  - But only guarantees soft real-time
- For hard real-time must also provide ability to meet deadlines
- Processes have new characteristics: periodic ones require CPU at constant intervals
  - Has processing time t, deadline d, period p
  - $0 \le t \le d \le p$
  - Rate of periodic task is 1/p

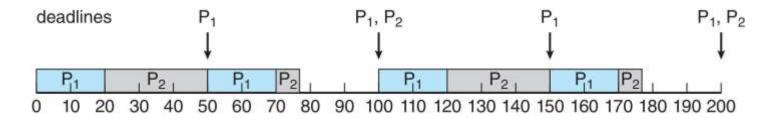

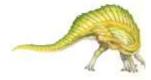

## Rate Monotonic Scheduling

- A priority is assigned based on the inverse of its period
- Shorter periods = higher priority;
- Longer periods = lower priority
- P<sub>1</sub> is assigned a higher priority than P<sub>2</sub>.

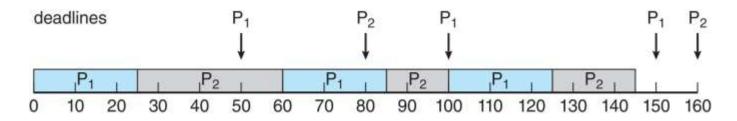

#### **Earliest Deadline First Scheduling (EDF)**

- Priorities are assigned according to deadlines:
  - The earlier the deadline, the higher the priority
  - The later the deadline, the lower the priority
- Figure

### **Algorithm Evaluation**

- How to select CPU-scheduling algorithm for an OS?
- Determine criteria, then evaluate algorithms
- Deterministic modeling
  - Type of analytic evaluation
  - Takes a particular predetermined workload and defines the performance of each algorithm for that workload
- Consider 5 processes arriving at time 0:

Process	<b>Burst Time</b>
$P_1$	10
$P_2$	29
$P_3$	3
$P_4$	7
$P_5$	12

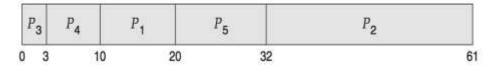

#### **Deterministic Evaluation**

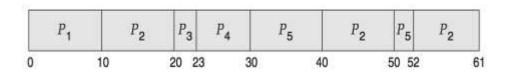

- For each algorithm, calculate minimum average waiting time
- Simple and fast, but requires exact numbers for input, applies only to those inputs
  - FCS is 28ms:

Non-preemptive SFJ is 13ms:

• RR is 23ms:

### **Queueing Models**

- Describes the arrival of processes, and CPU and I/O bursts probabilistically
  - Computes average throughput, utilization, waiting time, etc.
- Computer system described as network of servers, each with queue of waiting processes
  - Knowing arrival rates and service rates
  - Computes utilization, average queue length, average wait time, etc.

#### Little's Formula

- n = average queue length
- W = average waiting time in queue
- $\lambda$  = average arrival rate into queue
- Little's law in steady state, processes leaving queue must equal processes arriving, thus:

$$n = \lambda \times W$$

- Valid for any scheduling algorithm and arrival distribution
- For example, if on average 7 processes arrive per second, and normally 14 processes in queue, then average wait time per process = 2 seconds

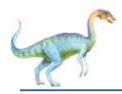

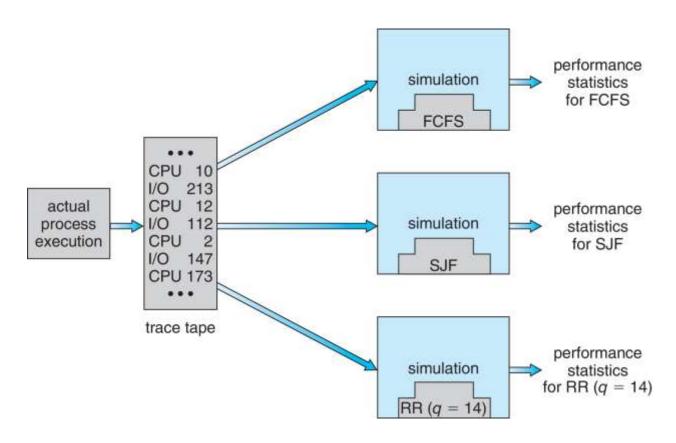

#### **Simulations**

- Queueing models limited
- Simulations more accurate
  - Programmed model of computer system
  - Clock is a variable
  - Gather statistics indicating algorithm performance
  - Data to drive simulation gathered via
    - Random number generator according to probabilities
    - Distributions defined mathematically or empirically

#### **Evaluation of CPU Schedulers by Simulation**

#### **Implementation**

- Even simulations have limited accuracy
- Just implement new scheduler and test in real systems
  - High cost, high risk
  - Environments vary
- Most flexible schedulers can be modified per-site or per-system
- Or APIs to modify priorities
- But again environments vary

# **End of Chapter 5**
